## Lecture 01: Introduction to Python

February 7, 2023

#### 1 Introduction to Python

Slides modified from Pierian Data

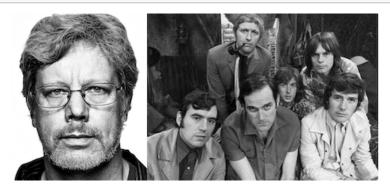

#### 2 What is Python and why use it

- high-level,
- interpreted,
- general-purpose programming language that is used for a wide range of applications.
- It is easy to learn, and
- powerful.

### 3 Why is it called Python?

When he began implementing Python, Guido van Rossum (left) was also reading the published scripts from "Monty Python's Flying Circus" (Right), a BBC comedy series from the 1970s. Van Rossum thought he needed a name that was short, unique, and slightly mysterious, so he decided to call the language Python. –General Python FAQ

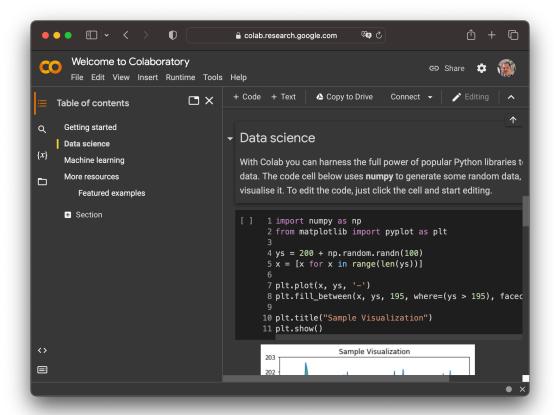

[1]: from IPython.display import display, Image display(Image(filename="images/python.png"))

# 4 Working with Python using Google Colab

Homepage: https://colab.research.google.com/ (runs online, cloud-computing like)

[2]: display(Image(filename="images/colab.png"))

### 5 Working with Python using JupyterLab Desktop

Homepage: https://github.com/jupyterlab/jupyterlab-desktop (runs offline, desktop)

```
[3]: display(Image(url="https://raw.githubusercontent.com/jupyterlab/

jupyterlab-desktop/master/media/jupyterlab-desktop.png"))
```

<IPython.core.display.Image object>

## 6 First Things First

As with any programming course, here is the Hello World! in Python.

```
[4]: print ("Hello World!")

Hello World!

[5]: display(Image(url="https://i.redd.it/zbqqkmy3kyqy.png", width = 400))
```

#### 7 Variable

A variable is a named storage location used to hold a value. The value of a variable can be changed and it can be used in expressions and operations

#### 8 Variable Assignment

- names can not start with a number
- names can not contain spaces, use \_ intead
- names can not contain any of these symbols:  $",<>/?|\!@#%^&*~-+$
- according to Style Guide for Python Code (PEP8), it's considered best practice that names are lowercase with underscores
- avoid using Python built-in keywords like list and str
- avoid using the single characters 1 (lowercase letter el), 0 (uppercase letter oh) and I (uppercase letter eye) as they can be confused with 1 and 0

## 9 Dynamic Typing

Python uses *dynamic typing*, meaning you can reassign variables to different data types. This makes Python very flexible in assigning data types; it differs from other languages that are statically typed.

```
[6]: my_cat = 2
my_cat
[6]: 2
```

```
[7]: my_cat = ['Basbousa', 'Lucy']
my_cat
```

```
[7]: ['Basbousa', 'Lucy']
```

### 10 Pros and Cons of Dynamic Typing

- Pros of Dynamic Typing
  - very easy to work with
  - faster development time
- Cons of Dynamic Typing
  - may result in unexpected bugs!

## 11 Assigning Variables

Variable assignment follows name = object, where a single equals sign = is an assignment operator

```
[8]: a = 5
a
```

[8]: 5

### 12 Reassigning Variables

Python lets you reassign variables with a reference to the same object.

```
[9]: a = a + 10
a
```

[9]: 15

There's actually a shortcut for this. Python lets you add, subtract, multiply and divide numbers with reassignment using +=, -=, \*=, and /=.

```
[10]: a += 10
a
```

[10]: 25

[11]: 50

## 13 Determining variable type with type()

You can check what type of object is assigned to a variable using Python's built-in type() function. Common data types include:

```
[12]: type(a)
```

[12]: int

#### 14 Numbers

Basically there are two types of numbers: - 2 is interger int - 2.0 is floating point float

Example	Number Type
1,2,-5,1000	Integers
1.2,-0.5,2e2,3E2	Floating point

```
[13]: type(2)
```

```
[13]: int
[14]: type(2.0)
[14]: float
          Basic Arithmetic 1/2
     15
[15]: 2+1 # Addition
[15]: 3
[16]: 2-1 # Subtraction
[16]: 1
[17]: 2*2 # Multiplication
[17]: 4
[18]: 3/2 # Division
[18]: 1.5
          Basic Arithmetic 2/2
[19]: 3//2 # Floor division (It returns the result of division rounded down to the
       ⇔nearest integer)
[19]: 1
[20]: 2**3 # Powers
[20]: 8
     Question: how to calculate the sequare root of 16?
          Order of Operations
[21]: 2 + 10 * 10 + 3
[21]: 105
[22]: (2+10) * (10+3)
[22]: 156
```

#### 18 Strings

Strings in Python are **text**, such as names, stored as a sequence or a list of characters. For example, Python understands the string 'AUC' to be a sequence of letters in a specific order. This means we will be able to use indexing to grab particular letters (like the first letter A, or the last letter C).

#### 19 Creating a String

To create a string in Python you need to use either single quotes ' or double quotes ".

```
[23]:
      'Hello'
[23]: 'Hello'
[24]:
      'Hello World!'
[24]:
      'Hello World!'
[25]:
      "This is also a string"
[25]: 'This is also a string'
[26]:
      'I'm using single quotes, but this will create an error'
         Cell In[26], line 1
           'I'm using single quotes, but this will create an error'
       SyntaxError: invalid syntax
 []: Now I\'m ready to use the single quotes inside a string!' # Using escape
       \hookrightarrow character
 []: "Now I'm ready to use the single quotes inside a string!" # Using double quotes
```

### 20 Printing a String

Using Jupyter notebook with just a string in a cell will automatically output strings, but the correct way to display strings in your output is by using a **print** function.

```
[]: 'Hello World'

[]: 'Hello World 1'
   'Hello World 2'

[]: print('Hello World 1')
   print('Hello World 2')
```

```
[]: print('Hello World 1\nHello World 2') # using \n for new line
```

## 21 String Indexing 1/3

Since strings are a sequence, we can use brackets [] after an object to call its index. We should also note that indexing **starts at 0** for Python.

```
[]: name = 'Emma'
name

[]: name[0]

[]: name[1]

[]: name[-1]
```

### 22 String Indexing 2/3

```
[]: name[:2]
[]: name[2:]
[]: name[::1]
```

### 23 String Indexing 3/3

```
[]: name[::2]
```

What will be the ouptut of name[::-1]

# 24 String Properties 1/3

String in Python are **immutable** i.e., once a string is created, the elements within it can not be changed or replaced.

```
[ ]: name
[ ]: name[0] = 'e'
```

## 25 String Properties 2/3

So if we need to change the value of a string, we will need to **reassign** it the new value:

```
[]: name = name + " Stone" name
```

```
[]: display(Image(url="https://api.time.com/wp-content/uploads/2016/12/

emma-stone-lalaland.jpg", width = 400))
```

### 26 String Properties 3/3

```
[]: name * 5
```

### 27 Bulit-in String Method

In Python, we can call objects' methods with a period and then the method name in the following form: object.method(parameters). And here are some built-in methods in strings:

```
[ ]: name.upper() # Convert to upper case
[ ]: name.lower() # Convert to lower case
[ ]: name.split() # Split by a separator (the default are white spaces)
[ ]: name.replace("m", "M")
[ ]: display(Image(url="https://miro.medium.com/v2/resize:fit:800/format:webp/\u000400*6GbsTL8b7L2EBvu1.jpg", width = 300))
[ ]: print("Thank you!")
```
